

Chapter 7 - Alkyl Halide & Substitution/ Elimination Rxns

Nomenclature

2-Bromo
2-methyl
pentane

2-bromo-2-methylpentane

(R)

1,1-dimethyl
2-chloro
cyclohexane

(R)-2-chloro-1,1-dimethylcyclohexane

Rules for Alcohols

Alcohol must be part of parent chain & have the lowest possible locant #.

2-ol
 5,5-dimethyl
 hexanol

5,5-dimethylhexan-2-ol ←
 5,5-dimethyl-2-hexanol ↗

1-ol
 2,2-dimethyl
 4-ethyl

(1R, 4S)

Cyclopentane ↗

(1R, 4S) - 4-ethyl-2,2-dimethylcyclopentan-1-ol

Types of positions

1°

Primary
(terminal)

2°

Secondary

Alkyl halide

Alcohol

3°

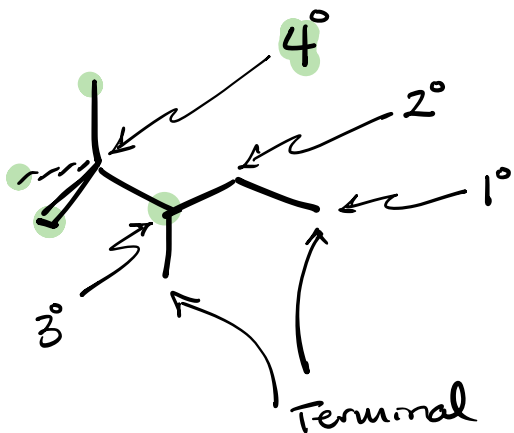

Tertiary

Vinyl
or
Vinylic

Allyl
or
Allylic

Propargyl
or
Propargylic

4° Quaternary

3° Tertiary

2° Secondary

1° Primary

Substitution Reactions

R = some molecule

LG = Leaving group (often a halide)

NUC = nucleophile

General Rate for all Substitution $3^\circ > 2^\circ > 1^\circ$ for R-LG
in relation to the position of the LG.

Examples

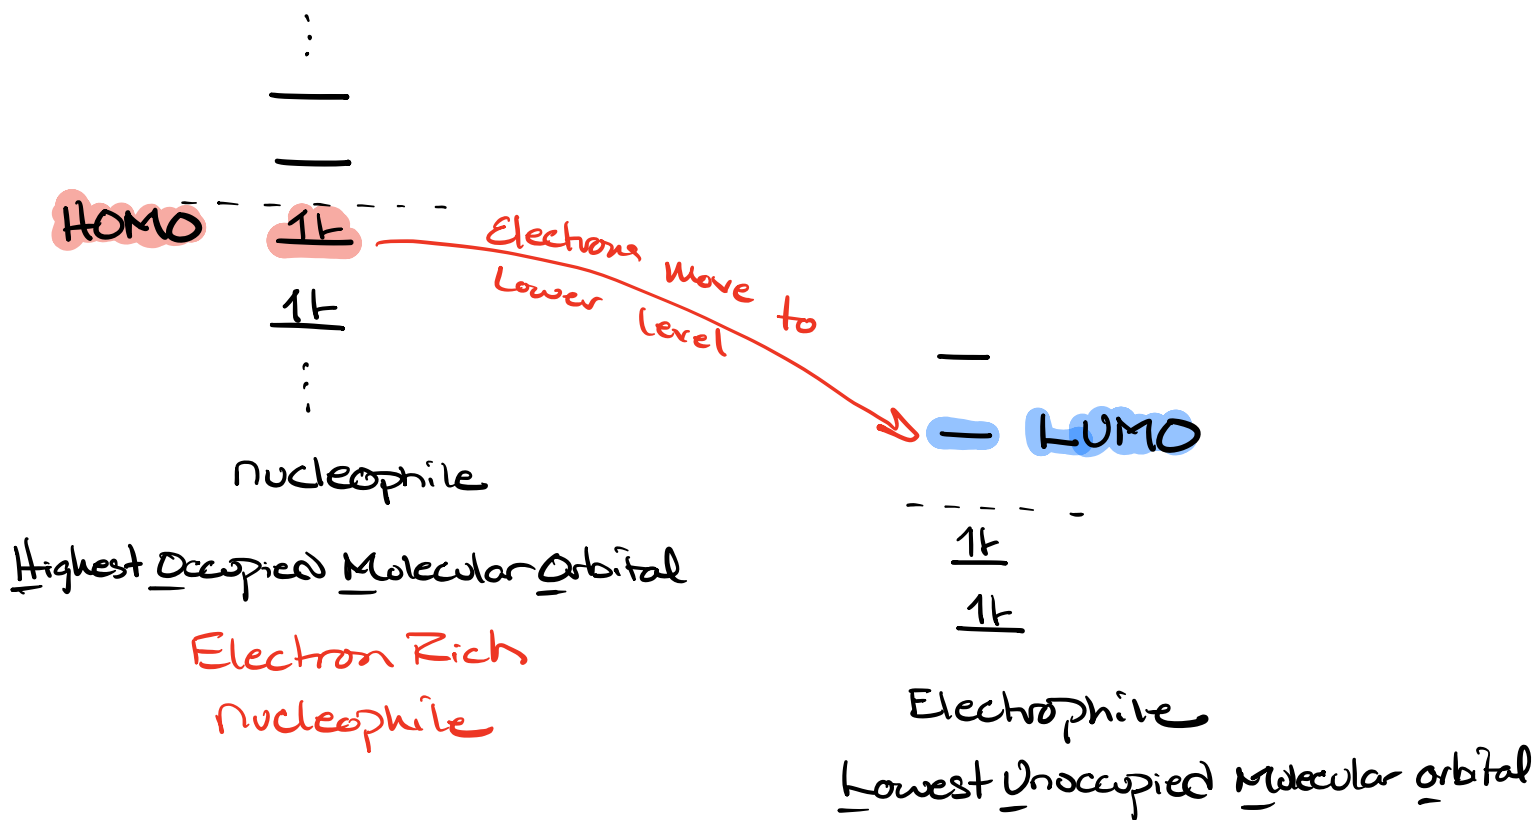

Δ = Capital Delta = Heat (usually Reflux)

Examples of S_N2

Reaction Theory

nucleophile

HOMO

Electrophile

Electron Poor Species
Electrophile

LUMO ???

What does LUMO look like?

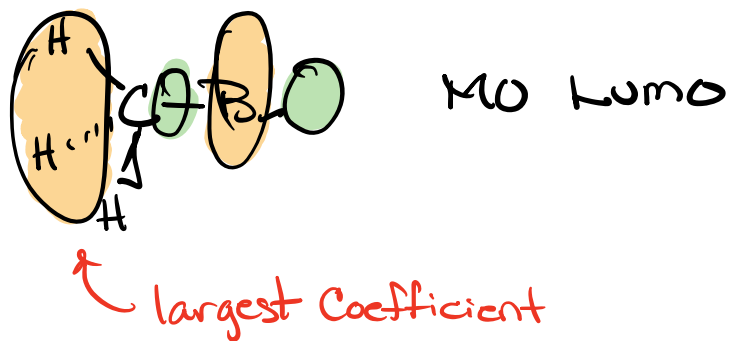

Two ways to look at the electrophile LUMO

① Valence Bonding theory (Natural Bonding theory)

σ^* antibonding for R-LG

Molecular Orbital Theory

* Electrons from nucleophile must be placed into σ^* to disrupt and break the σ bond

For S_N2 ~~Reaction~~ both models show that the nucleophile must attack the "back side" of the carbon with the LG to reach the σ^* .

must attack "back side"
